Modeling Mach Number and Temperature Distributions in Supersonic Nozzle Flow

Joseph Majdalani* and Brian A. Maicke†
University of Tennessee Space Institute, Tullahoma, TN 37388

Stodola’s area-Mach number relation is one of the most widely used expressions in compressible flow analysis. From academia to aero-propulsion, it has found utility in the design and performance characterization of numerous propulsion systems; these include rockets, gas turbines, micro-combustors, and micro-thrusters. In this study, we derive a closed form approximation for the inverted and more commonly used solution relating performance directly to the nozzle area ratio. The inverted expression provides a computationally efficient alternative to solutions based on traditional lookup tables and root finding. Here both subsonic and supersonic Mach numbers are obtained explicitly as a function of the area ratio and the ratio of specific heats. The corresponding recursive formulations enable us to specify the desired solution to any level of precision. In closing, a dual verification is achieved using a CFD simulation of a typical nozzle and through Bosley’s formal approach intended to confirm the truncation error entailed in our approximations. In this process, both asymptotic and numerical solutions are compared for the Mach number and temperature distributions throughout the nozzle.

Nomenclature

\[
\begin{align*}
A & = \text{local cross sectional area} \\
A_t & = \text{nozzle throat area} \\
E_n & = \text{absolute error between } M_N \text{ and } M_n \\
M_n & = \text{asymptotic property at iteration order } n \\
M_N & = \text{numeric property reflecting true value} \\
e & = \text{perturbation parameter, } A_t / A \\
\gamma & = \text{ratio of specific heats}
\end{align*}
\]

Subscripts and Symbols

\[
\begin{align*}
0, 1 & = \text{leading and first order} \\
c & = \text{condition in the combustion chamber} \\
e & = \text{condition in the exit plane} \\
n & = \text{asymptotic level} \\
N & = \text{numerically calculated value} \\
t & = \text{condition at the nozzle throat} \\
s & = \text{subsonic term}
\end{align*}
\]

I. Introduction

The design of a supersonic nozzle may be viewed as an optimization study in which the exit Mach number plays the role of a target variable defined by mission requirements. In this vein, a wide variability exists as virtually any smooth curve can be used in the subsonic region so long as the concavity of the contracting section does not prompt flow separation. In the throat section, curvature is minimized to promote the establishment of a uniform
choke plane. Downstream of the throat, the flow is accelerated to supersonic levels across an expanding section. In this region, proper contouring becomes critically important as discontinuities in the Prandtl-Meyer angle can cause undesirable shocks and expansions. In the vicinity of the exit plane, the curvature is re-straightened to reduce flow divergence losses. While traditional techniques, such as the method of characteristics, can be employed to arrive at an optimal nozzle shape, computational fluid dynamics (CFD) can also be used as a modern alternative.

In addition to the geometric optimization challenges, thermal protection issues arise in practical nozzle manufacture. These are often associated with the temperature distribution and heat fluxes resulting at the walls. On the one hand, enhancing performance and payload capability entails reducing weight and tapering edges. On the other hand, thermal protection against exhaust gases requires strong materials and optimally designed cross sections. To gradually straighten the flow out of the nozzle, a relatively long, slowly sloping skirt is required to the extent that choosing a suitable length becomes an optimization process in its own right, specifically, one that gauges weight constraints, geometry, and divergence losses. It can thus be seen that the initial design phase of a nozzle relies on an iterative process in which a multitude of calculations are required and where isentropic tools can be readily employed due to their ease and relative accuracy.

During this iterative process, several isentropic flow approximations in converging-diverging nozzles may be used and these are based on the area-Mach number relation connecting the Mach number to the nozzle area ratio and gas properties. Since its inception in 1903 by Stodola, this key expression has led to a substantial leap in our understanding of supersonic nozzle behavior; today, it can be found in most fundamental textbooks on the subject.

Stodola’s relation has been verified both experimentally and more recently via CFD. It is used in compressible flow simulations of the internal flowfield in solid rocket motors by Cheng, Liu and Sirignano, Jackson, Najjar and Buckmaster, and Stewart et al. It appears in one segment of Rocflu, a compressible Navier-Stokes solver intended for simulating rocket internal ballistics. It is also used in characterizing turbomachinery, scarred and contoured-plug nozzles, pulse detonation engines, and magnetohydrodynamic systems. More recently, it has been employed in applications of constructal theory by Bejan, and in modeling micro-thrusters and micro-combustors by Leach and Tosin. Its popularity as a simple design tool lies in its ability to predict the area ratio needed to produce a desired exit flow Mach number. This feature is, however, not analytically invertible due to the transcendental nature of the Mach number dependence. At present, one must resort to tabulation or root finding in the process of estimating the expected exit Mach number for fixed area ratio and specific gas properties. In this study, we overcome this difficulty through the use of asymptotics.

The inversion of a Mach number relation via asymptotics is not a novel concept. In similar context, the Prandtl-Meyer function has been treated by a number of researchers such as Probst in developing a hybrid inversion using a mix of analytical and computational tools. While these methods vary from those employed here, they lend support to the usefulness of analytical approximations for problems that arise in similar physical contexts. The present relation will be derived with a sufficient degree of accuracy to serve as a direct and practical design alternative. Not only will this solution increase our repertoire of known approximations for compressible flow models, but it will also provide a simple alternative to tabulation and root finding.

II. Formulation

For isentropic flow through a converging-diverging nozzle with throat area \( A_t \), a transcendental equation relates the area ratio, \( \varepsilon = A_t / A \), and the local Mach number \( M \) at any cross section of surface area \( A \). We are particularly interested in the so-called nozzle expansion ratio for which \( A \) corresponds to the maximum area \( A_t \) in the nozzle exit plane. From an asymptotic perspective, this condition results in the smallest possible \( \varepsilon = \varepsilon_r \). In order to calculate the exit Mach number for a given nozzle design ratio, one can solve for \( M \) using a numerical root finding technique appropriate for

\[
\varepsilon \left[ 1 + \frac{1}{2} (\gamma - 1) M^2 \right]^{\frac{\gamma+1}{2(\gamma-1)}} - M \left[ 1 + \frac{1}{2} (\gamma - 1) \right]^{\frac{\gamma+1}{2(\gamma-1)}} = 0
\]  

(1)

In general, \( \gamma \) varies between 1.1 and 1.67. In rocket motors, \( \gamma \) varies between 1.1 and 1.4 with an average value of 1.25. For example, the Reusable Solid Rocket Motor (RSRM) has an average molecular weight \( M_w = 28.46 \text{ kg/kmol} \), constant specific heats \( C_p = 1966.54 \text{ J/kg-K} \) and \( C_v = 1674.4 \text{ J/kg-K} \), a specific gas constant \( R = 292.14 \text{ J/kg-K} \), a mean chamber pressure \( p_0 = 6.28 \text{ MPa} \), a ratio of specific heats \( \gamma = 1.17 \), and an

2 American Institute of Aeronautics and Astronautics
exit area ratio \( \varepsilon_c = 0.13 \). The exit Mach number is typically larger than 2 and can, of course, be calculated from Eq. (1). According to Sutton,\textsuperscript{7} the exit value can range from as low as 2.5 to as high as 10, with most being in a 4-6 range. What is important is that, in many applications, the area ratio \( \varepsilon_c \) varies between 1/3 and 1/25.\textsuperscript{7} For high altitude applications (100 km or higher), \( \varepsilon_c \) ranges between 1/400 and 1/40; here the exit areas are increased to accommodate expansions to lower external pressures. To be conservative, one may then assume
\[ 0.002 \leq \varepsilon_c \leq 0.4 \]  
(2)

The natural emergence of a small quantity \( \varepsilon \) is the motivation for using perturbation methods. These permit the construction of asymptotic solutions for the area-Mach number \( M = M(\varepsilon, \gamma) \) that encapsulate both roots of Eq. (1).

Once the Mach number is determined it can be used to predict the spatial evolution of the temperature, pressure, and density throughout the nozzle. Because Stodola’s equation remains an idealized case, it may be used in conjunction with isentropic relations such as,
\[ T = T_c \left[ 1 + \frac{\gamma - 1}{2} (\gamma - 1) M^2 \right]^{\frac{\gamma}{\gamma - 1}}, \quad p = p_c \left[ 1 + \frac{\gamma - 1}{2} (\gamma - 1) M^2 \right]^{\frac{1}{\gamma - 1}}, \quad \rho = \rho_c \left[ 1 + \frac{\gamma - 1}{2} (\gamma - 1) M^2 \right]^{\frac{1}{\gamma - 1}} \]  
(3)
where \( p_c, T_c, \) and \( \rho_c \) stand for stagnation chamber properties. Clearly, substitution of \( M = M(\varepsilon, \gamma) \) in the above will give rise, by direct extension, to \( T = T(\varepsilon, \gamma, T), p = P(\varepsilon, \gamma, p_c), \) and \( \rho = \Theta(\varepsilon, \gamma, \rho_c) \).

The pressure and temperature are of chief interest because the pressure determines, in part, how the nozzle performs for a given geometry, and the construction of the nozzle is dependent, in part, on the wall temperature distribution and its induced thermal gradients. To illustrate these effects, Fig. 1 is used to describe the pressure and temperature distributions in an isentropic nozzle. In this graph, the subsonic pressures and temperatures are seen to exhibit qualitatively similar shapes, starting at a maximum value and decreasing as the flow enters the converging section of the nozzle. The temperature decreases rather gradually as the acceleration in the subsonic region builds progressively. After the flow crosses the throat at \( \varepsilon = 1 \), the pressures and temperatures continue to decrease. In the case of the pressure, the supersonic branch appears to mirror its subsonic counterpart, with the slight asymmetry being caused by the location of the critical pressure at the throat, here shown for \( \gamma = 1.4 \). The temperature, however, experiences visibly dissimilar trends. As the flow enters the supersonic region, the temperature steadily decreases, for \( \varepsilon \approx 1 \), and then drops precipitously as the area ratio approaches zero. This behavior can be attributed to the thermal-to-kinetic energy conversion and its sensitivity to the degree of area expansion. For small values of \( \varepsilon \), the substantial gain in Mach number is seen to translate into appreciable temperature differentials, specifically in the nozzle exit section.

### III. Analysis

For a fixed area ratio, two Mach numbers are possible depending on whether the axial position is located upstream or downstream of the throat section. In what follows, the asymptotic analysis leading to each of these roots is described.

#### A. Subsonic Solution

Using \( \varepsilon \) as our perturbation parameter, an explicit series approximation for the subsonic Mach number, \( \bar{M} = \bar{M}(\varepsilon, \gamma) \), can be pursued. The subsonic series approximation can be obtained using regular perturbations. To
It may be later shown that this expression is virtually indiscernible from the numerical solution of the problem. In fact, for operational area ratios up to $\varepsilon = 0.47$ and $\gamma = 1.7$, only one term needs to be calculated and still secure a practical approximation that accrues a less than 5% error. Table 1 catalogues the maximum value of $\varepsilon$ for which the error will remain bracketed under 5% at different values of $\gamma$ and the first three asymptotic orders. Note that the range of validity broadens when more terms are retained or when $\gamma$ is lowered. The range extends to $\varepsilon = 0.50$ for the lowest value reported, $\gamma = 1.1$. Using a two-term correction, the maximum operational range increases to $0.64 \leq \varepsilon \leq 0.79$ for $1.1 \leq \gamma \leq 1.7$, with the largest $\varepsilon$ corresponding to the smallest $\gamma$. From an engineering perspective, Eq. (15) mirrors the exact solution because

\begin{table}[h]
\centering
\caption{Maximum nozzle area ratio with less than 5\% relative error at increasing asymptotic orders}
\begin{tabular}{|c|c|c|c|}
\hline
\textbf{a} & \textbf{Subsonic} & \textbf{Supersonic} \\
\hline
\textbf{\gamma} & 0 & 1 & 2 & 0 & 1 & 2 \\
\hline
1.1 & 0.495 & 0.794 & 0.889 & n/a & 0.948 & 0.987 \\
1.2 & 0.491 & 0.670 & 0.885 & n/a & 0.767 & 0.999 \\
1.3 & 0.486 & 0.664 & 0.883 & n/a & 0.729 & 0.962 \\
1.4 & 0.482 & 0.658 & 0.881 & n/a & 0.0631 & 0.746 & 0.940 \\
1.5 & 0.478 & 0.653 & 0.879 & n/a & 0.01890 & 0.773 & 0.931 \\
1.7 & 0.470 & 0.644 & 0.875 & n/a & 0.06470 & 0.820 & 0.930 \\
\hline
\end{tabular}
\end{table}

American Institute of Aeronautics and Astronautics
its error remains smaller than that associated with the governing equation itself; the latter is attendant on the isentropic flow idealization. Hence, by virtue of the physical range defined in Eq. (2), a one-term approximation is sufficient to provide an accurate approximation up to $\varepsilon = 0.40$, $\forall \gamma$. This key result is:

$$\bar{M} \approx \varepsilon \left[ (\gamma + 1) \left( \frac{1}{(\gamma - 1)} \right)^{1/(\gamma - 1)} + \mathcal{O}(\varepsilon^2) \right]$$

(16)

Note that $\varepsilon$ is not limited to the nozzle expansion ratio. It may correspond to any cross section so long as the inverted ratio with the throat area remains small.

B. Supersonic Solution

Using the method of successive approximations, an explicit series expansion for $M = M(\varepsilon, \gamma)$ may be obtained. Successive approximations may be applied to polynomials and transcendental relations in which roots are not deducible from a regular expansion, namely, from a predetermined sequence of gauge functions. The ensuing linearization may be achieved by striking a balance in Stodola’s equation between terms that dominate for $M > 1$. To this end, we rewrite Eq. (1) in supersonic notation by introducing the three constants $\beta$, $\kappa$, and $\mu$:

$$\beta = (\gamma + 1)/(\gamma - 1); \kappa = \sqrt{\gamma/(\gamma - 1)}; \mu = \varepsilon^{\beta/\gamma} / \sqrt{1 + \kappa^2}$$

(17)

These may be substituted into Eq. (1) to render the simple form

$$\mu^2 \left( 1 + \kappa^2 M^2 \right) = M^{2\beta}$$

(18)

Next, $M$ must be expanded carefully. In identifying the leading order part of Eq. (18), we substitute $M_0 = X_0$ into Eq. (18) and write

$$X_0^{2\beta} - \mu^2 \kappa^2 X_0 - \mu^2 = 0$$

(19)

A scaling analysis reveals that the first two members of Eq. (19) dominate with the third member representing a secondary contribution. This behavior can be confirmed through the use of a numerically calculated root. For the supersonic case at $\varepsilon = 0.1$, the Mach number is $\mathcal{O}(1)$. When substituting the ordered quantities back into Eq. (19), the first member will be seen to carry the largest contribution. Along similar lines, the second member will exhibit a non-negligible, albeit smaller contribution, owing to its coefficient $\mu^2 = \varepsilon^{2\beta}$ multiplying its $X_0^2 > 1$ part. The third member in Eq. (19) contains an $e^{2\beta}$ term only; as such, it can be viewed as a higher order quantity. It is important to note that by balancing the first two members, a different leading order equation is achieved. At leading order, the two largest terms will balance when

$$X_0 = (\mu \kappa)^{2(1/\gamma - 1)} + \mathcal{O}(\varepsilon^{2(1/\gamma - 1)})$$

(20)

Successive expansions of $M$ may be similarly undertaken by setting $M_i = X_0 + X_i$. Backward substitution into Eq. (18) leads to a solution for $X_i$ bearing a truncation error of $\mathcal{O}(\varepsilon^{2(1/\gamma - 1)})$. For all approximations past $X_0$, a recurrence relation may be written for $X_i$ in terms of $X_i-1$:

$$X_i = \lambda \left[ M_{i-1}^\beta \left( M_{i-1}^{2\beta} - M_{i-1}^\beta \beta \kappa^2 \mu^2 \right) 
+ M_{i-1}^{2\beta} \kappa^2 \mu^2 (2\beta - 4\beta + 4) - M_{i-1}^\beta \beta^2 \kappa^2 \mu^4 + M_{i-1}^{4\beta} (2\beta - 3) + 2 M_{i-1}^{2\beta} \mu^2 (2 - \beta) \right]^{1/2}; i \geq 1$$

(21)

where

$$\lambda = \frac{1}{2 M_{i-1}^{2\beta} (\beta - 2) + M_{i-1}^\beta \beta^2 \kappa^2 \mu^2}$$

(22)

The higher order solutions may be sequentially obtained from the straightforward sum

$$M_n = X_0 + X_1 + \ldots + X_n$$

(23)

Table 1 also lists the area ratios for which the relative error in Eq. (23) will reach 5% at different perturbation orders. To maintain a less than 5% error, a two-term approximation is clearly necessary as the validity of one term expressions is limited. Using $M_i = X_0 + X_i$, the relevant range of area ratios extends to $[0.73 \ldots 0.95]$ depending on the value of $\gamma$. When three terms are held, the valid range is extended to 0.99 at $\gamma = 1.2$. Considering that practical nozzles do not exceed $\varepsilon = 0.4$, a two-term approximation of the form $M = M_1$ may be relied on.

Before leaving this section, it may be interesting to note that the $\gamma$-dependence differs in behavior between the subsonic and supersonic solutions. In the former, the range of validity in $\varepsilon$ improves at lower values of $\gamma$. In the latter, more than one local minimum can appear due to the nonlinearity of the supersonic formulation. For $M = M_1$, a local minimum appears in the middle of the feasible range of $\gamma$, occurring approximately near $\gamma = 1.3$. The corresponding range of validity in $\varepsilon$ subsequently expands as $|\gamma - 1.3|$ is increased.
IV. Comparison and Order Verification

A. Numerical Verification

The approximation for $M_n$ is compared in Fig. 2 to $M_N$, the numerical solution of Eq. (1), at increasing asymptotic orders, $n = 0, 1, 2$. Both $M_N$ and $M_n$ are shown in subsonic and supersonic regimes at a representative value of $\gamma = 1.4$. These trends remain unchanged at other $\gamma$. The inset in Fig. 2 enhances the differences between numerics and asymptotics in the transonic region. In the meaningful range of $\epsilon \leq 0.4$, the visible discrepancies become indiscernible when using either the one-term subsonic or the two-term supersonic approximations. This behavior concurs with the relative error predictions (reflecting a less than 5% deviation) furnished in Table 1 for $M_0$ and $M_1$. In the vicinity of $\epsilon = 1$, the discrepancies do not pose a concern as they only denote impractically small nozzle divergences.

B. CFD Verification

An inviscid, axisymmetric, density-based, double precision, finite volume solver is employed to simulate the motion of an ideal gas in a fully-flowing supersonic nozzle. The nozzle has inlet and outlet area ratios of 2.42 and 5.44, respectively. Given an overall nozzle length of $L = 0.3$ m, the computational domain is resolved using a mesh comprised of 26,801 quadrilateral cells, as shown in Fig. 3. The nozzle contour consists of a simple three-point spline. Using air as the working fluid, two separate validation runs are undertaken. The first trial uses a low pressure, low temperature flow with $c_{300K}, T_{300K} = 300 K$, while the second simulates a higher chamber pressure and a temperature of $T_{2,200K} = 2,200 K$. The thermodynamic properties specific to each trial are posted in Table 2.

Figure 4 describes the evolution of the velocity vectors and corresponding Mach numbers for the low temperature trial. The velocity scatter and Mach number contours characterize the flow magnification through the converging-diverging nozzle (Figs. 4a-b). Downstream of the throat section, in the supersonic acceleration stage, the particles at the wall outrun the centerline particles. This can be attributed to the absence of friction at the wall and the enhanced radial and axial expansions near the wall due to nozzle divergence; these exceed the centerline expansion that is limited to axial acceleration alone. Being expanded both axially and radially, the flow near the wall experiences increased values of the local Mach number. Conversely, the axially dominated centerline motion undergoes no radial acceleration and, as such, remains limited to a relatively smaller increase in its local Mach number.

The wall, centerline, and average Mach numbers obtained at different stations in the nozzle are compared in Fig. 4c to the three-term analytical approximations. This comparison is carried out point-by-point and shows that the 1-D analytical model lies between the wall and centerline curves, thus providing excellent agreement with the average computed Mach number at any given station. This agreement holds everywhere except in the close vicinity of the throat.

where the solution begins to diverge as the area ratio approaches unity. This region can be further shrunk by including more corrective terms, although the three-term approximation remains adequate over the vast majority of the nozzle.

Figures 5 and 6 display the thermal data for the low and high chamber temperature runs. As expected, the spatial distribution of the temperature isolines are qualitatively comparable to the Mach number contours, both for the cold (Fig. 5) and hot (Fig. 6) simulations. The temperatures undergo a constant decline as the fluid is accelerated throughout the nozzle, owing to the continual thermal-to-kinetic energy conversion. Figures 5b and 6b compare both trials to the present study using the isentropic relation in Eq. (3). As with the Mach number, the asymptotic approximations are seen to provide an excellent average throughout the nozzle, with small discrepancies being detected in the neighborhood of the throat. The resulting expressions can thus be used as analytical alternatives to

Figure 3. CFD nozzle geometry and mesh selection with enlarged inset.
CFD computations in simplified thermal analyses of the nozzle. For example, both Stodola’s and CFD solutions predict the occurrence of the maximum heat flux just upstream of the sonic point where the centerline velocity first reaches the speed of sound. This behavior is consistent with experiments and may be seen in Fig. 7 where the normalized heat flux, defined by \( q = T_l (2\pi r) \), is plotted over the length of the nozzle using Stodola’s numerical solution, the present approximation, and CFD predictions. Also shown on the same graph is the spatial variation of the Mach number obtained from Stodola’s 1-D model previously described in Fig. 4.

C. Asymptotic Error Verification

To verify the order of the error associated with the subsonic and supersonic perturbation expansions of \( M \), one may apply Bosley’s graphical technique. Accordingly, one may confirm that the expansion is asymptotically valid by showing that its absolute error exhibits, in some range of \( \varepsilon \), a constant logarithmic rate. For that purpose, the absolute error may be defined as

\[
E_n(\varepsilon, \gamma) = |M_n - M_N|, \quad E_r = |\bar{M}_n - \bar{M}_N| \quad (24)
\]

In either of the subsonic or supersonic cases, if the truncation error appears at order \( r \), one can put

\[
E_n(\varepsilon, \gamma) = C \varepsilon^r \quad (25)
\]

Graphically, the order of a given approximation can then be inferred from the log-log plot of \( E_n \) versus \( \varepsilon \) at constant \( \gamma \). According to Bosley, it is important for the error to approach zero at the correct rate (i.e., \( r \to \text{const} \) ) as \( \varepsilon \to 0 \).

Forthwith, graphs of \( \log E_n \) versus \( \log \varepsilon \) are given in Fig. 8 over a practical range of nozzle area ratios and a representative value of \( \gamma = 1.4 \). Corresponding asymptotic slopes are obtained using linear least-squares and posted in Table 3, including those for \( \gamma = 1.2 \). It is gratifying to note that all slopes approach constant rates, thus reflecting an ‘error-free’ analysis.

In the subsonic case, the best fit slopes obtained from least-squares match quite closely the order of the theoretical truncation error given by Eq. (14).

In the supersonic case, the slope begins at a modest rate of descent that can be approximated by \( \frac{1}{2} (\gamma - 1) \). It then increases rapidly as more terms are added. By retaining two terms, the asymptotic order in \( M_1 \) jumps to \( 4(\gamma - 1)/(\gamma + 1) \). Being almost quadrupled in comparison to the leading order, \( M_1 \) is accompanied by a less than 5% error for practical values of \( \gamma \) and up to \( 0.73 \leq \varepsilon \leq 0.95 \) (Table 1). In the supersonic case, the order increases with \( \gamma \). In every case, the slope approaches a constant value with a higher correlation coefficient at higher values of \( n \) and in ranges of smaller \( \varepsilon \). The slopes shown in Table 3 are evaluated in the \( \varepsilon \in [0.001–0.01] \) domain. Their agreement with the theoretical orders only improves in ranges of smaller \( \varepsilon \).

Figure 4. Cold flow simulation results depicting a) velocity vector distribution, b) Mach number contours, and c) comparison of Mach number predictions.
V. Conclusions

In this work, two asymptotic approximations are presented as practical equivalents to the numerically-inverted area-Mach number relation. The present analysis provides the explicit dependence of the Mach number on the nozzle area ratio and ratio of specific heats. This dependence illuminates the influence of each of these parameters on the maximum achievable Mach number for isentropic motion. They also facilitate the efficient evaluation of thermodynamic properties while carrying out a performance analysis of a De Laval nozzle. The present results are hoped to be further used in deriving closed-form expressions of other related parameters in compressible flow studies, which often assume inviscid motions. Were viscous effects included in the analysis, they would have resulted in a reduced average velocity, especially near the wall where the flow would be decelerated. If such were the conditions, then Stodola’s relation could still provide a good approximation for the Mach number and corresponding temperature distributions near the centerline, where viscous effects are least significant.
